

HYDROSEEDING EXPERIMENT DONE BY DR. T.L.SENN

This experiment was designed to simulate the use of 1 gallon of Nature's NOG to hydro-seed one acre.

One hundred seeds were planted in each container. The chart below shows that, when treated with NOG, more seeds germinated and the treated seeds developed into larger plants sooner than the untreated "control". The photo shows the difference in plant growth.

The media was washed from each sample and the dried samples were weighted. The dry weight of the control sample was 1.26 grams and the NOG treated sample weighed 2.09 grams.

METHOD: Add one gallon of Nature's NOG to the hydro-seeder tank, add 100 gallons of water and add the seed. Allow the seeds to soak for 5 – 10 minutes. Add the rest of the water and any other ingredients to seed one acre.
